

File permissions in Linux

Project description

Managing the permission of the projects in the organization.

Check file and directory details

To check the directory and file details, we write:

```
ls -la
```

To get all the permissions of the files and folders in that directory.

Describe the permissions string

The 10-character string that would be a part of the output is `drwxrwxrwx`, which indicates a directory if the first character is `d`; otherwise, it is `-`.

The permission string contains three divisions: user, group, and other, each having read, write, and execute permissions.

Change file permissions

To change the permissions, we use the command `chmod`, which changes the mode of the file or the directory.

The organization does not allow others to have write permission.

From the current file permissions, we have write permission for files in the other division. They are:

```
project_k.txt
```

We can use the command:

```
chmod o-w project_k.txt
```

To remove the write permission.

Change file permissions on a hidden file

To change the permission of the hidden file, we use:

```
chmod u-w .project_k.txt
```

Change directory permissions

To change the permission of the directory, we use:

```
chmod g+r,g+w draft
```

Summary

In this activity, I checked file and directory permissions using the `ls -la` command. I reviewed the permission strings to understand user, group, and other access. I used the `chmod` command to modify file and directory permissions and remove unauthorized write access. These steps help ensure that only authorized users have access to files and directories in the system.
